MD5HashDescription: The MD5 hash is a widely used secure hash algorithm (the successor of the MD4 hash algorithm) designed by the United States National Security Agency (NSA) for use in the Secure Hash Algorithm (SHA). The MD5 algorithm was designed to produce 128-bit output, but the algorithm can be used to create 256-bit output by adding an additional round of the hash function. Sha1Description: The Secure Hashing Algorithm 1 (SHA-1) is a cryptographic hash function and a project of the National Security Agency (NSA) in the United States, to develop a secure message digest for use in the Advanced Encryption Standard (AES) algorithm. The algorithm was first published in 1996, and has been widely used in secure messaging, internet transactions, software development, and other security applications. NTLMDescription: NTLM (Network Time-Locked Key Management) is a network authentication protocol designed to establish key establishment and secrets between two parties in a network communication. The initial version of NTLM was published by Microsoft in 1997. MySQLHashDescription: The MySQL hash function is designed by Martin Burnett of MySQL AB. It is an extension to the MD5 algorithm that produces 128-bit output, and is intended to serve as a replacement for the MD5 and SHA-1 hashes in MySQL. SHA256Description: The Secure Hash Algorithm 256 (SHA-256) is a cryptographic hash function that was developed and submitted by the National Security Agency (NSA) for the Secure Hash Algorithm (SHA). It was designed by NSA to be at least 256 bits long, and is a replacement for MD5, SHA-1, and SHA-224 in most applications. The SHA-256 function is a significantly strengthened variant of SHA-256, which is designed to be resistant against preimage and second preimage attacks.
